

## PLEASE TAKE NOTE OF THE FOLLOWING POINTS

Following this guide will ensure that you get the best out of your newly installed premium tint film

Weather dependant, the applied tint film can take between 2-3 weeks to fully adhere to the glass and for the adhesive to fully cure, this due to the fact that glass is non porous. During this time the tint film should not be disturbed, cleaned or tampered with, as ultimately it will affect the final outcome. As the tint film is applied with an application liquid and pressure, this could cause haziness and or small bubbles 2mm, this is perfectly normal and will disappear as the tint film fully cures.

It is always good practice to regularly inspect the applied tint film to ensure that all is in order. Any loose or peeling areas should be attended to immediately.

## Window Washing

**HAND WASH** your windows with a soft cloth or sponge and a mild soapy water. If the windows are heavy soiled rinse as much dirt off as possible before wash, as this reduce scratches on the film. Once washed and rinsed dry off excess water to reduce spotting.

## Chemicals

**DO NOT** use abrasive or acid based chemicals to clean your tinted windows, although no noticeable difference can be seen the constant use will shorten the lifespan and some discolouring of your tint film will occur. A mild soapy water ie dish wash liquid is ideal, one can put a few drops (5ml / 1 teaspoon) methylated spirits to minimise streaking on the windows. A soft cloth, ie micro fibre or lint free cloth should be used, no abrasive or scratch pads.

## Tint Film Removal

Using a blade, start in a corner and carefully pull the film away (this takes a bit of patience), enough so that you can grab the film with you fingers, pull at an angle, less than 90degrees, supporting the glass with the other hand. There will be some glue residue left on the glass once the film has been removed, which can be removed with thinners or methylated spirits.
